

Rebased on [3a](#) — pretrained model, bring-your-own imagery, F-cover is the output

Corrected model F-Cover ships with a pretrained canopy model. A user drops in their own imagery, the model pre-labels it, corrections feed a fine-tune, and the deliverable is the fractional cover % table—not a ground-truth archive. Some Subterra patterns remain on a new image domain (yam UAV plots), plotted plants on a bench with ruler + colour chart, greenhouse trays) and it quantifies that domain too. So the “Accept as ground truth” button becomes *fine correction* → *fine-tune* set, and the domain the model is running in is now stated at the top of every screen.

Try next: “add the cover results table + CSV export for [3a](#).” “Show batch pre-label progress right after upload?” “make [3b](#) a full on-plot wizard instead of a status page”

3 Yam F-Cover —three GUI directions

Assumption: the daily job is review + correct, not annotate+fine-tune—the model pre-labels a batch of clipped plot TIFFs and a familiar wizard through accepting or invalidating flows, then exports cover maps. So the three directions differ mainly in what the screen is organized around: the single plot (3a), the model/cor-CD, or the whole field trial (3c). Every image area is a placeholder—fine-tune orthophotos later. Nothing here needs your filesystem.

3c. Field Notebook—light, pipeline-centric review station. Warm paper, neutrals, more metadata, one plot at a time with keyboard+fast accept/inspect.

3d. Field Lab—something console. Model registry, training runs and live inference logs, somewhat console is one page among testaments.

3e. Trial Grid—both-map first. The trial layout. A, the reorganizer a plingrid heatmap of hover with a review drawer, so objects surface before you open anything.

Try next: “expand [3a](#) into the full annotate flow (upload → batch pre-label → review)” “make [3b](#) the home screen and 3a to detail view” “new directions—something less dashboard-y”
